

A FORMULA FOR SOLVING GENERAL QUINTICS; A FOUNDATION FOR SOLVING GENERAL POLYNOMIALS OF HIGHER DEGREES

ABSTRACT

I explore possible methods of solving general quintics and higher degree polynomials. In this paper I will attempt to show that each quintic has an auxiliary cubic equation. I will therefore attempt to bring a method of deriving a general quintic and its possible auxiliary cubic equation forms. I propose the same method to be used to generate higher degree polynomials.

AUTHORS NAME: SAMUEL BONAYA BUYA

KEY WORDS: Radical Solution of general quintics and other higher degree polynomials, Disproof of Abel’s impossibility theorem; formula solutions of irreducible quintics.

METHOD

Consider the simple cubic equation:

$$x^3 = x + 2 \text{ ----- 1}$$

Squaring both sides of the above equation we obtain the equation:

$$x^6 = (x + 2)^2 = x^2 + 4x + 4 \text{ ----- 2}$$

Multiplying both sides of equation 1 by x^3 we obtain the equation:

$$x^6 = (x + 2)x^3 = x^4 + 2x^3 \text{ ----- 3}$$

Subtracting equation 2 from 1 and rearranging we obtain the equation:

$$x^4 + 2x^3 - x^2 - 4x - 4 = 0 \text{ ----- 4}$$

Rearranging equation 1:

$$x^3 - x - 2 = 0 \text{ ----- 5}$$

The cubic equation 5 is an auxiliary equation of the quartic equation 4 since:

$$x^4 + 2x^3 - x^2 - 4x - 4 = (x^3 - x - 2)(x - 2) = 0 \text{ ----- 6}$$

This analysis projects the idea that each polynomial equation possesses auxiliary lower degree polynomial. I will use this concept to come up with a method that can be used to solve any general quintic.

Consider the cubic equation:

$$x^3 = (x + a)^2 + bx + c = x^2 + x(b + 2a) + a^2 + c \text{ ----- 7}$$

Again consider the cubic equation:

$$x^3 = x^2 + dx + e \text{ ----- 8}$$

Multiplying equation 8 by 7 we obtain the equation:

$$x^6 = x^4 + x^3(b + 2a + d) + x^2(a^2 + c + e + bd + 2ad) + x(dc + be + 2ae + a^2d) + ce \text{ -----9}$$

Multiplying both sides of equation 7 by x^3 we obtain the equation:

$$x^6 = x^5 + x^4(b + 2a) + x^3(a^2 + c) \text{ ----- 10}$$

Multiplying both sides of equation 8 by x^3 we obtain the equation:

$$x^6 = x^5 + x^4d + x^3e \text{ ----- 11}$$

Taking equation 10 subtracting equation 9 and rearranging:

$$x^5 + x^4(b + 2a - 1) + x^3(a^2 + c - b - 2a - d) - x^2(a^2 + c + e + bd + 2ad) - x(dc + be + 2ae + a^2d) - ce = 0 \text{ ----- 13}$$

I will call equation 13 an extended quintic equation.

Rewriting the cubic equations 7 and 8:

$$x^3 - x^2 - x(b + 2a) - a^2 - c = 0 \text{ ----- 14}$$

$$x^3 - x^2 - dx - e = 0 \text{ ----- 15}$$

The product of equation 7 and 8 is given by:

$$[x^3 - \{(x + a)^2 + bx + c\}][x^3 - x^2 - dx - e] = 0 \text{ ----- 16}$$

Equation 10 can be rewritten as:

$$(x^3 + (x + a)^2 + bx + c)x^3 - x^6 = ((x + a)^2 + bx + c)x^3 = 0 \text{ ----- 17}$$

Adding equation 16 to 17 and simplifying we get the equation:

$$x^3(-x^2 - dx - e) - \{(x + a)^2 + bx + c\}(-x^2 - dx - e) = 0$$

$$\text{Or } [x^2 + dx + e][x^3 - \{(x + a)^2 + bx + c\}] = 0 \text{ ----- 18}$$

The expansion of equation 18 is given by

$$x^5 + x^4(d - 1) + x^3(b - 2a - d + e) + x^2(c - a^2 + d(b + 2a) - e) + x[d(c - a^2) + e(b - 2a)] + e(c - a^2) = 0 \text{ ----- 19}$$

Equation 19 is a second extended general quintic whose factorized form is equation 18.

The second extended general quintic can be used to obtain a general quintic formula since

$$a_4 = d - 1 \text{ ----- 19}$$

$$a_3 = b - 2a - d + e \text{ ----- 20}$$

$$a_2 = c - a^2 + d(b + 2a) - e \text{ ----- 21}$$

$$a_1 = d(c - a^2) + e(b - 2a) \text{ ----- 22}$$

$$a_0 = e(c - a^2) \text{ ----- 23}$$

By equation 19:

$$d = a_4 + 1 \text{ ----- 24}$$

$$\text{Let } p = c - a^2 \text{ ----- 25}$$

$$\text{Let also } q = (b - 2a) \text{ ----- 26}$$

$$\text{Then } a_3 = p - (a_4 + 1) + e \text{ ----- 27}$$

$$a_2 = p + (a_4 + 1)q - e \text{ ----- 28}$$

$$a_1 = p(a_4 + 1) + eq \text{ ----- 29}$$

Equation 23 can be written as:

$$a_0 = -ep \text{ ----- 30}$$

Substituting 30 into 26 and simplifying:

$$p^2 - p(a_4 + a_3 + 1) + a_0 = 0 \text{ ----- 31}$$

$$p = \frac{(a_4 + a_3 + 1) \pm \sqrt{(a_4 + a_3 + 1)^2 - 4a_0}}{2} \text{ ----- 31}$$

By equation 30:

$$e = \frac{-a_0}{p} \text{ ----- 33}$$

By equation 28:

$$q = \frac{a_2 + e - p}{a_4 + 1} \text{ ----- 34}$$

To determine b and c, choose a and then calculate b and c using the equations 25 and 26

Example 1

$$\text{Solve } x^5 - x + 1 = 0$$

Solution

$$a_4 = 0 \Rightarrow d = 1$$

$$p = \frac{1 \pm \sqrt{1-4}}{2} = \frac{1 \pm i\sqrt{3}}{2}$$

$$\text{Take } p = \frac{1+i\sqrt{3}}{2}$$

$$e = \frac{2}{1+i\sqrt{3}}$$

$$q = e - p = \frac{3-i\sqrt{3}}{1+i\sqrt{3}}$$

$$\text{Take } a=1; c = p + 1 = \frac{3+i\sqrt{3}}{2}$$

$$b = q + 2 = \frac{5+i\sqrt{3}}{1+i\sqrt{3}}$$

The auxiliary equations of the quintic are:

$$x^2 + x + \frac{2}{1+i\sqrt{3}} = 0$$

$$x^3 - x^2 + \frac{3-i\sqrt{3}}{1+i\sqrt{3}}x + \frac{1+i\sqrt{3}}{2} = 0$$

The above two quadratic and cubic equations can be solved by their respective formulae.

The roots of the auxiliary quadratic equation are:

$$x_{1,2} = \frac{-1}{2} \pm \sqrt{\frac{-7+i\sqrt{3}}{4(1+i\sqrt{3})}}$$

One of the roots of the auxiliary cubic equation is:

$$x_3 = \sqrt[3]{\frac{4}{27} + \sqrt{\frac{16}{729} + \frac{1}{27} \left(\frac{-3+i\sqrt{3}}{3(1+i\sqrt{3})}\right)^3}} - \sqrt[3]{\frac{4}{27} + \sqrt{\frac{16}{729} + \frac{1}{27} \left(\frac{-3+i\sqrt{3}}{3(1+i\sqrt{3})}\right)^2} + \frac{1}{3}}$$

CONCLUSION

A general formula for solving quintics is achievable. Irreducible quintics can be solved by the formula method proposed. Given a_0, a_1, a_2, a_3 and a_4 one can determine a, b, c, d, e and hence solve the quintic equation.
